ECE 6552 – Lecture 2[1]

ESSENTIALLY NONLINEAR PHENOMENA

January 9 2025

Additional Reading:

- Khalil, Chapter 2

Overview

- List several phenomena unique to systems that are not linear

- Phase portraits in the plane

Review

Last class we ended with the pendulum example. Note, we assumed that there was a frictional force resisting the motion that was proportional to the speed of the mass (i.e., $F_{ext} = -kv = -k\ell\dot{\theta}$).

This allowed us to derive the equations of motion:

From the Lagrangian
$\mathcal{L}(\theta, \dot{\theta}) = \frac{1}{2}m\ell^2\dot{\theta}^2 - mg\ell\cos\theta$

$$\frac{d}{dt}\left(\frac{\partial\mathcal{L}}{\partial\dot{\theta}}\right) - \frac{\partial\mathcal{L}}{\partial\theta} = \tau_{ext}$$

$$\frac{d}{dt}\left(m\ell^2\dot{\theta}\right) + mg\ell\sin\theta = -k\ell^2\dot{\theta}$$

$$m\ell^2\ddot{\theta} + mg\ell\sin\theta = -k\ell^2\dot{\theta}$$

$$\ddot{\theta} + \frac{g}{\ell}\sin\theta = -\frac{k}{m}\dot{\theta}$$

$$\ddot{\theta} = -\frac{k}{m}\dot{\theta} - \frac{g}{\ell}\sin\theta$$

From these equations of motion, we can derive a state-space representation of the system by defining the state variables $x_1 = \theta$ and $x_2 = \dot{\theta}$:

$$\dot{x}_1 = x_2$$

$$\dot{x}_2 = -\frac{k}{m}x_2 - \frac{g}{\ell}\sin x_1$$

or in matrix form:

$$\dot{x} = \begin{bmatrix} x_2 \\ -\frac{k}{m}x_2 - \frac{g}{\ell}\sin x_1 \end{bmatrix}$$

We can identify the equilibrium points of the system by identifying x^* such that $f(x^*) = 0$:

$$x^* = \{(0,0), (\pi,0)\}$$

Finally, the we can determine the stability of the equilibrium points by linearizing our system around each of the equilibrium points:

$$A = \frac{\partial f}{\partial x}\Big|_{x^*} \triangleq \begin{bmatrix} \frac{\partial f_1}{\partial x_1} & \frac{\partial f_1}{\partial x_2} \\ \frac{\partial f_2}{\partial x_1} & \frac{\partial f_2}{\partial x_2} \end{bmatrix}\Big|_{x^*}$$

$$A = \begin{bmatrix} 0 & 1 \\ -\frac{g}{\ell}\cos x_1 & -\frac{k}{m} \end{bmatrix}$$

$$J((0,0)) = \begin{bmatrix} 0 & 1 \\ -\frac{g}{\ell} & -\frac{k}{m} \end{bmatrix} \longrightarrow \Re(\lambda_i(A)) < 0 \quad \text{(stable)}$$

$$J((\pi,0)) = \begin{bmatrix} 0 & 1 \\ \frac{g}{\ell} & -\frac{k}{m} \end{bmatrix} \longrightarrow \Re(\lambda_1(A)) < 0, \Re(\lambda_2(A)) > 0 \text{(unstable)}$$

This example demonstrates a situation in which linearization is a valid approach towards analyzing a nonlinear system. As stated in Khalil, "whenever possible, we should make use of linearization to learn as much as we can about the behavior of a nonlinear system". However, linearization has two basic limitations:

- Linearization is only valid in a neighborhood of the equilibrium point ("local approximation").

- Nonlinear system dynamics are much richer than the dynamics of a linear system.

The following are phenomena that can only take place in the presence of nonlinearities and cannot be captured by linear models.
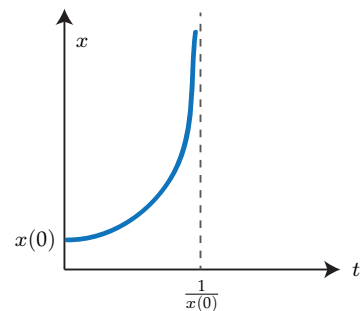

Essentially Nonlinear Phenomena

1. Finite Escape Time: (the state goes to infinity in finite time)
   Example: $\dot{x} = x^2$

$$\frac{dx}{dt} = x^2$$

$$\frac{1}{x^2}dx = dt$$

$$-\frac{1}{x} = t + C$$

$$x(t) = \frac{1}{C - t}$$

$$x(t) = \frac{1}{\frac{1}{x_0} - t}$$

$$\Rightarrow t_{\text{escape}} = \frac{1}{x_0}$$

For linear systems, $x(t) \to \infty$ cannot happen in finite time.

2. Multiple Isolated Equilibria

   Linear systems: either unique equilibrium or a continuum

   Pendulum: two isolated equilibria (one stable, one unstable)

   "Multi-stable" systems: two or more stable equilibria

   Example: bistable switch

   $$\dot{x}_1 = -ax_1 + x_2 \qquad x_1: \text{ concentration of protein}$$
   $$\dot{x}_2 = \frac{x_1^2}{1+x_1^2} - bx_2 \qquad x_2: \text{ concentration of mRNA}$$

   $a > 0$, $b > 0$ are constants. State space: $\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}$.

   This model describes a positive feedback where the protein en-
   coded by a gene stimulates more transcription via the term $\frac{x_1^2}{1+x_1^2}$.

   Single equilibrium at the origin when $ab > 0.5$. If $ab < 0.5$, the line
   where $\dot{x}_1 = 0$ intersects the sigmoidal curve where $\dot{x}_2 = 0$ at two
   other points, giving rise to a total of three equilibria:

stable	unstable	stable
(gene off)	(saddle point)	(gene on)

3. Limit cycles: Linear oscillators exhibit a continuum of periodic
   orbits; *e.g.*, every circle is a periodic orbit for $\dot{x} = Ax$ where
   $$A = \begin{bmatrix} 0 & -\beta \\ \beta & 0 \end{bmatrix} \qquad (\lambda_{1,2} = \mp j\beta).$$

   In contrast, a limit cycle is an isolated periodic orbit and can occur
   only in nonlinear systems.

   harmonic oscillator   limit cycle

Example: van der Pol oscillator (models a system with self-sustained oscillations)

$$
\begin{aligned}
C\dot{v}_C &= -i_L + v_C - v_C^3 \\
L\dot{i}_L &= v_C
\end{aligned}
$$

$$i_R = -v_C + v_C^3$$

"negative resistance"

4. Chaos: Irregular oscillations, never exactly repeating.

Example: Lorenz system (derived by Ed Lorenz in 1963 as a simplified model of convection rolls in the atmosphere):
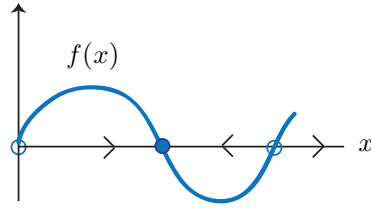

$$
\begin{aligned}
\dot{x} &= \sigma(y - x) \\
\dot{y} &= rx - y - xz \\
\dot{z} &= xy - bz.
\end{aligned}
$$

Chaotic behavior with $\sigma = 10$, $b = 8/3$, $r = 28$:

- For continuous-time, time-invariant systems, $n \geq 3$ state variables required for chaos.

  $\underline{n = 1}$: $x(t)$ monotone in t, no oscillations:
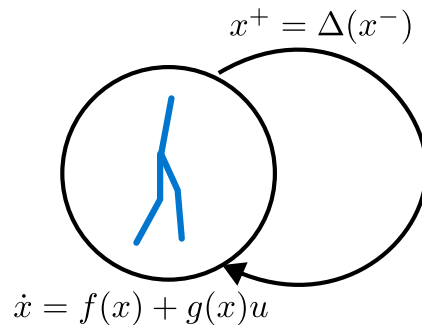

<u>$n = 2$:</u> Poincaré-Bendixson Theorem (to be studied in Lecture 4) guarantees regular behavior.

- Poincaré-Bendixson does not apply to time-varying systems and $n \geq 2$ is enough for chaos (for Van der Pol oscillator can exhibit chaos).

- For discrete-time systems, $n = 1$ is enough (we will see an example in Lecture 6).

5. Multiple modes of behavior:

   Hybrid systems exhibit both continuous and discrete dynamics. Examples include a bouncing ball, or a legged robot.

$$x^+ = \Delta(x^-)$$

$$\dot{x} = f(x) + g(x)u$$
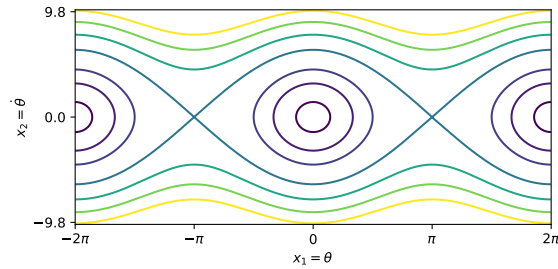

Planar (Second Order) Dynamical Systems

Chapter 2 in both Sastry and Khalil

$$\dot{x}_1 = f_1(x_1, x_2)$$
$$\dot{x}_2 = f_2(x_1, x_2)$$

Second-order autonomous systems are convenient to study because solution trajectories (i.e., $x(t) = x_1(t), x_2(t)$) can be represented as curves in the plane. This "plane" is usually called the *phase plane* with $f(x)$ the *vector field* on the phase plane.

The family of all trajectories (solution curves) is called the *phase portrait* of the system. For example, recall that the phase portrait of the pendulum system was:

Phase Portraits of Linear Systems: $\dot{x} = Ax$

Depending on the eigenvalues of A, the real Jordan form $J = T^{-1}AT$ has one of three forms:
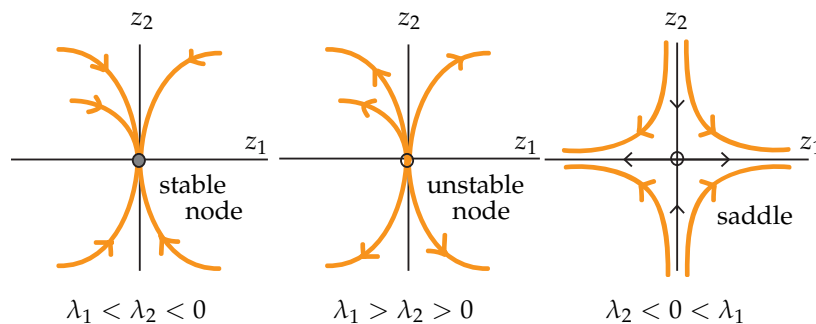

- Distinct real eigenvalues

$$T^{-1}AT = \begin{bmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{bmatrix}$$

In $z = T^{-1}x$ coordinates:

$$\dot{z}_1 = \lambda_1 z_1, \quad \dot{z}_2 = \lambda_2 z_2.$$
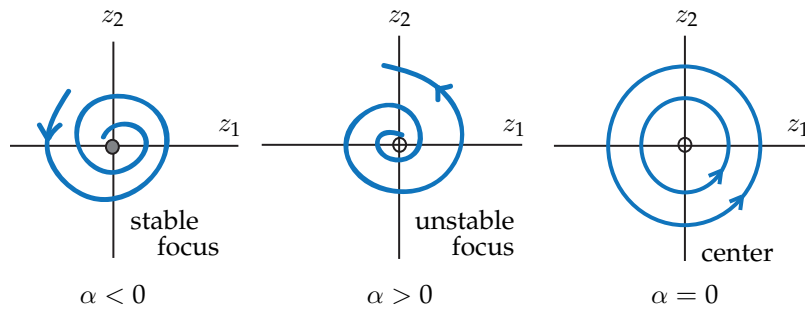

The equilibrium is called a *node* when λ_1 and λ_2 have the same sign (*stable* node when negative and *unstable* when positive). It is called a *saddle point* when λ_1 and λ_2 have opposite signs.

- Complex eigenvalues: $\lambda_{1,2} = \alpha \mp j\beta$

$$T^{-1}AT = \begin{bmatrix} \alpha & -\beta \\ \beta & \alpha \end{bmatrix}$$

$$\begin{matrix} \dot{z}_1 = \alpha z_1 - \beta z_2 \\ \dot{z}_2 = \alpha z_2 + \beta z_1 \end{matrix} \quad \rightarrow \quad \text{polar coordinates} \quad \rightarrow \quad \begin{matrix} \dot{r} = \alpha r \\ \dot{\theta} = \beta \end{matrix}$$

The phase portraits above assume $\beta > 0$ so that the direction of rotation is counter-clockwise: $\dot{\theta} = \beta > 0$.
